State Forecasts

Western Washington: Partly cloudy, with a few showers tonight and tomorrow. Snow on the mountain passes. High tomorrow, 46 to 54; low tonight, 35 to 45.

Mountain areas: Freezing level dropping to about 3,000 or 4,000 feet tonight and tomorrow, with rain changing to snow above 3,000 feet. Snow flurries on the east slopes of the Cascades.

Eastern Washington: Rain, beginning in the southwest, becoming general by tonight with increasing winds. Partly cloudy and cooler tomorrow, with snow flurries over the mountains. High tomorrow, 42 to 52; low tonight, 35 to 45.

Marine Warnings

Gale warnings were hoisted on the following waters:

- Inland—southeast winds 30 to 45 knots, diminishing tonight.
- Strait—northeast winds 35 to 45 knots, shifting to southwest or west and diminishing tonight.
- Whole-gale warnings were displayed on the coast from Tatoosh to Astoria for southeast winds 50 to 60 knots, diminishing to 34 to 46 tonight and 23 to 34 tomorrow.

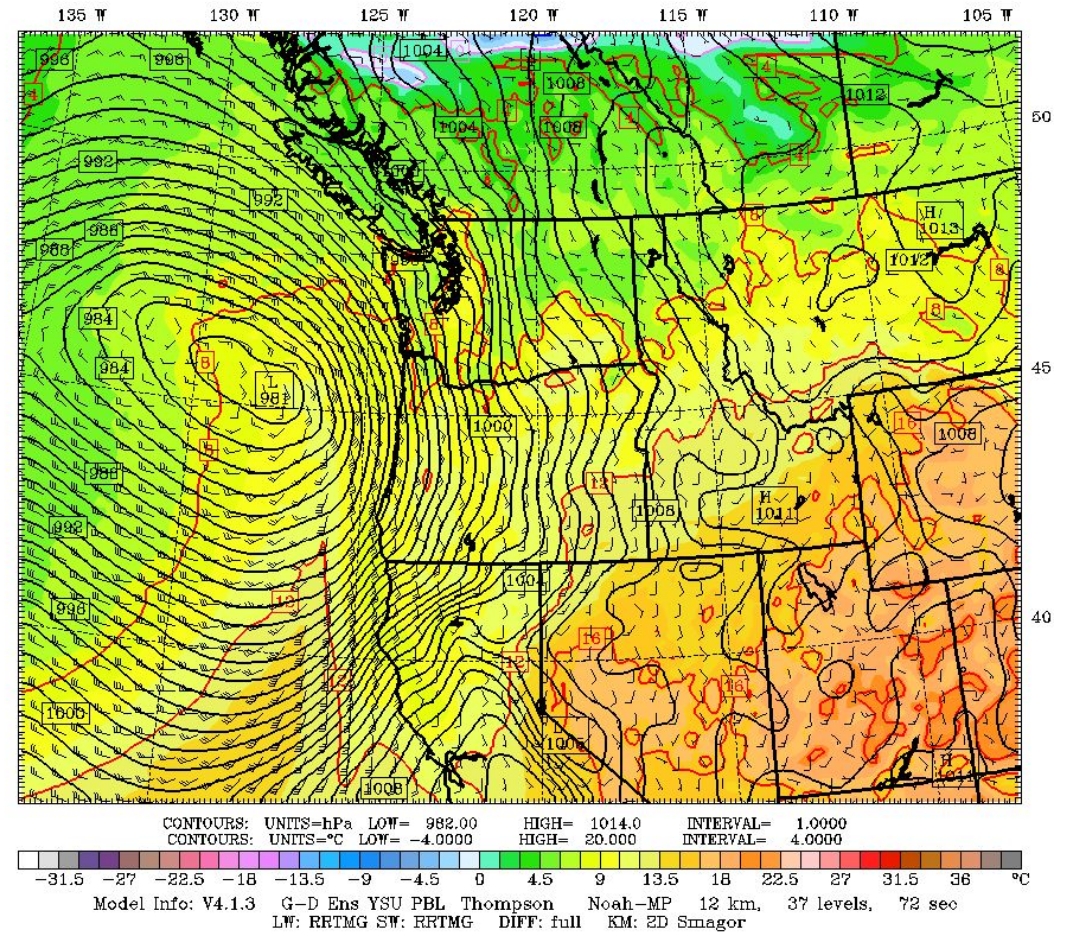

Attempts to simulate with modern models and data assimilation failed

Clearly there was a problem with the initial state over the Pacific (and other oceans) before the satellite era.

Observations were inadequate

Does RO data improve weather forecasts?

Show drafts 

Yes, Radio Occultation (RO) data significantly improves weather forecasts. 

RO data provides high-resolution vertical profiles of atmospheric temperature, pressure, and humidity. These profiles are crucial for accurate weather prediction models. Here's why: 

- **Improved understanding of atmospheric structure:** RO data helps meteorologists better understand the vertical structure of the atmosphere, including the boundary layer, troposphere, stratosphere, and mesosphere. 
- **Enhanced tropical cyclone forecasts:** RO data has been shown to improve forecasts of tropical cyclone intensity and track. 
- **Better prediction of extreme weather events:** By providing more accurate atmospheric data, RO can help improve predictions of severe weather events like hurricanes, thunderstorms, and heavy rainfall. 
- **Real-time monitoring of atmospheric conditions:** RO data can be collected in real-time, providing meteorologists with up-to-date information for making timely weather forecasts and warnings. 

In essence, RO data offers a valuable tool for improving weather prediction capabilities and ensuring public safety. 

Major improvement (1995-2008) following by the **great plateau in large-scale forecast skill**

Anomaly Correlation Coefficient - G004/Northern Hemisphere 20N-80N
500 hPa Geopotential Height (gpm)
valid 1984-2023 valid 00Z, Forecast Day 5 (Hour 120)
Yearly Mean

Does the “great plateau” mean that actual forecast skill has stagnated?

The Answer is No

Why? Because of ANOTHER NWP revolution that occurred as the great plateau become evident

Revolutions**

The High-Resolution Prediction Revolution

- During the past two decades, model resolution and physics improved substantially, allowing more accurate simulation of critical mesoscale features.
- In the U.S., global models went from ~ 100 km grid spacing in 1995 to 13 km in ~2020. National and regional models went from ~50 to ~4 km during the same period.

The Hand Off

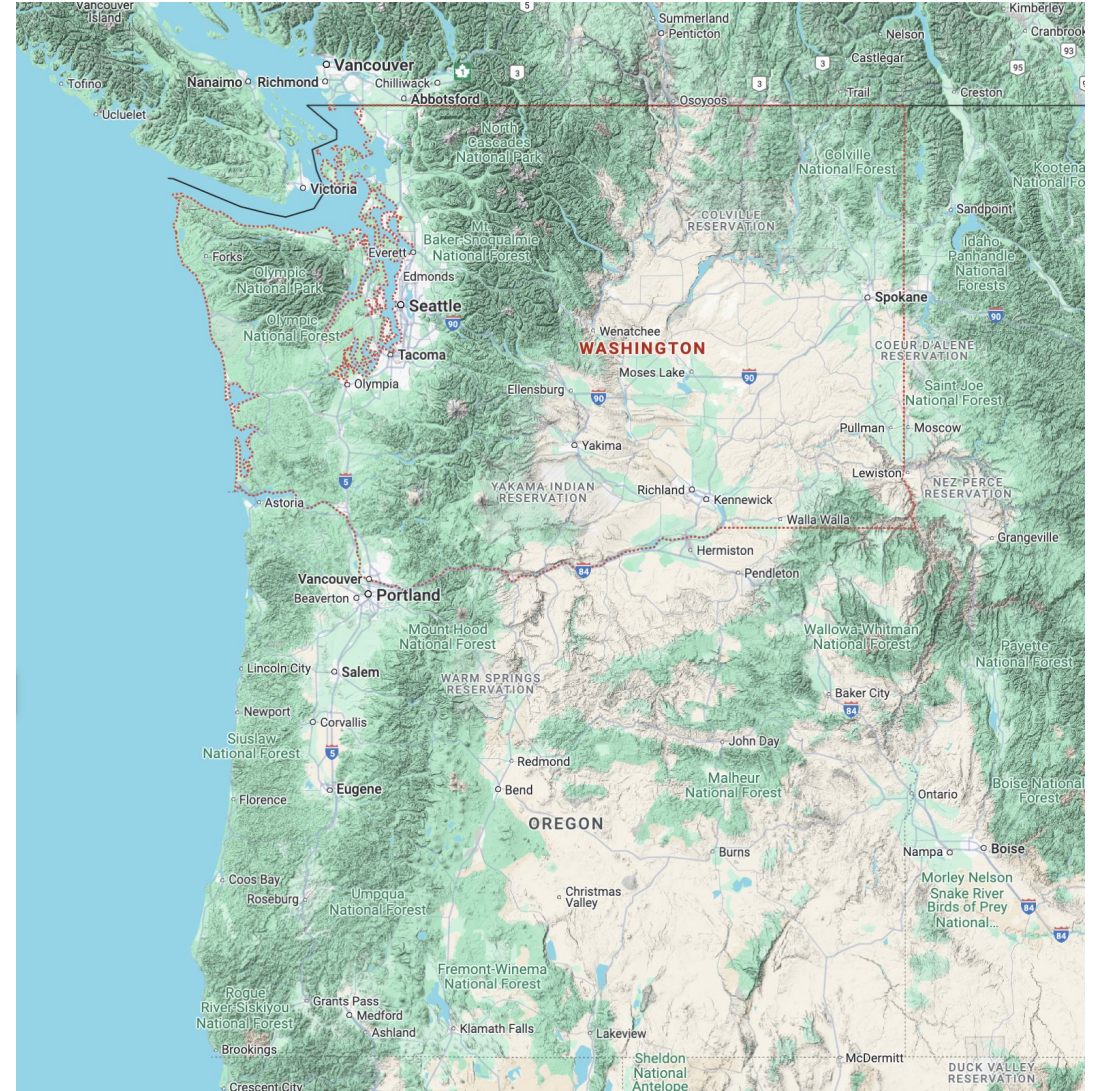

Using improved global data assimilation and prediction as a starting point, high resolution prediction provided increasingly skillful downscaling of global forecasts.

1995 State of the Art Operational Prediction: the NOAA/NWS NGM Model

No Mesoscale Structures

When grid spacings declined to ~15 km amazing things happened. Example: mesoscale terrain effects

24-h Precipitation ending 00 UTC 23 February 2024 WRF

100-km Grid Spacing

12-km Grid Spacing

But it was more than that.. At higher resolution...

- Frontal collapse and frontal circulations become resolved
- Downslope windstorms were simulated
- Convection increasingly resolved
- Diurnal circulations were simulated
- And much more...

A Stunning Example of Progress

On August 8, 2023, large wildfires hit western and central Maui, killing at least 100 people and resulting in 3-6 billion dollars of damage

The Maui Wildfire Event Was Associated with Very Strong Downslope Winds

Based on damage and limited wind observations, estimated winds gusted to 60-80 kt in and east of Lahaina

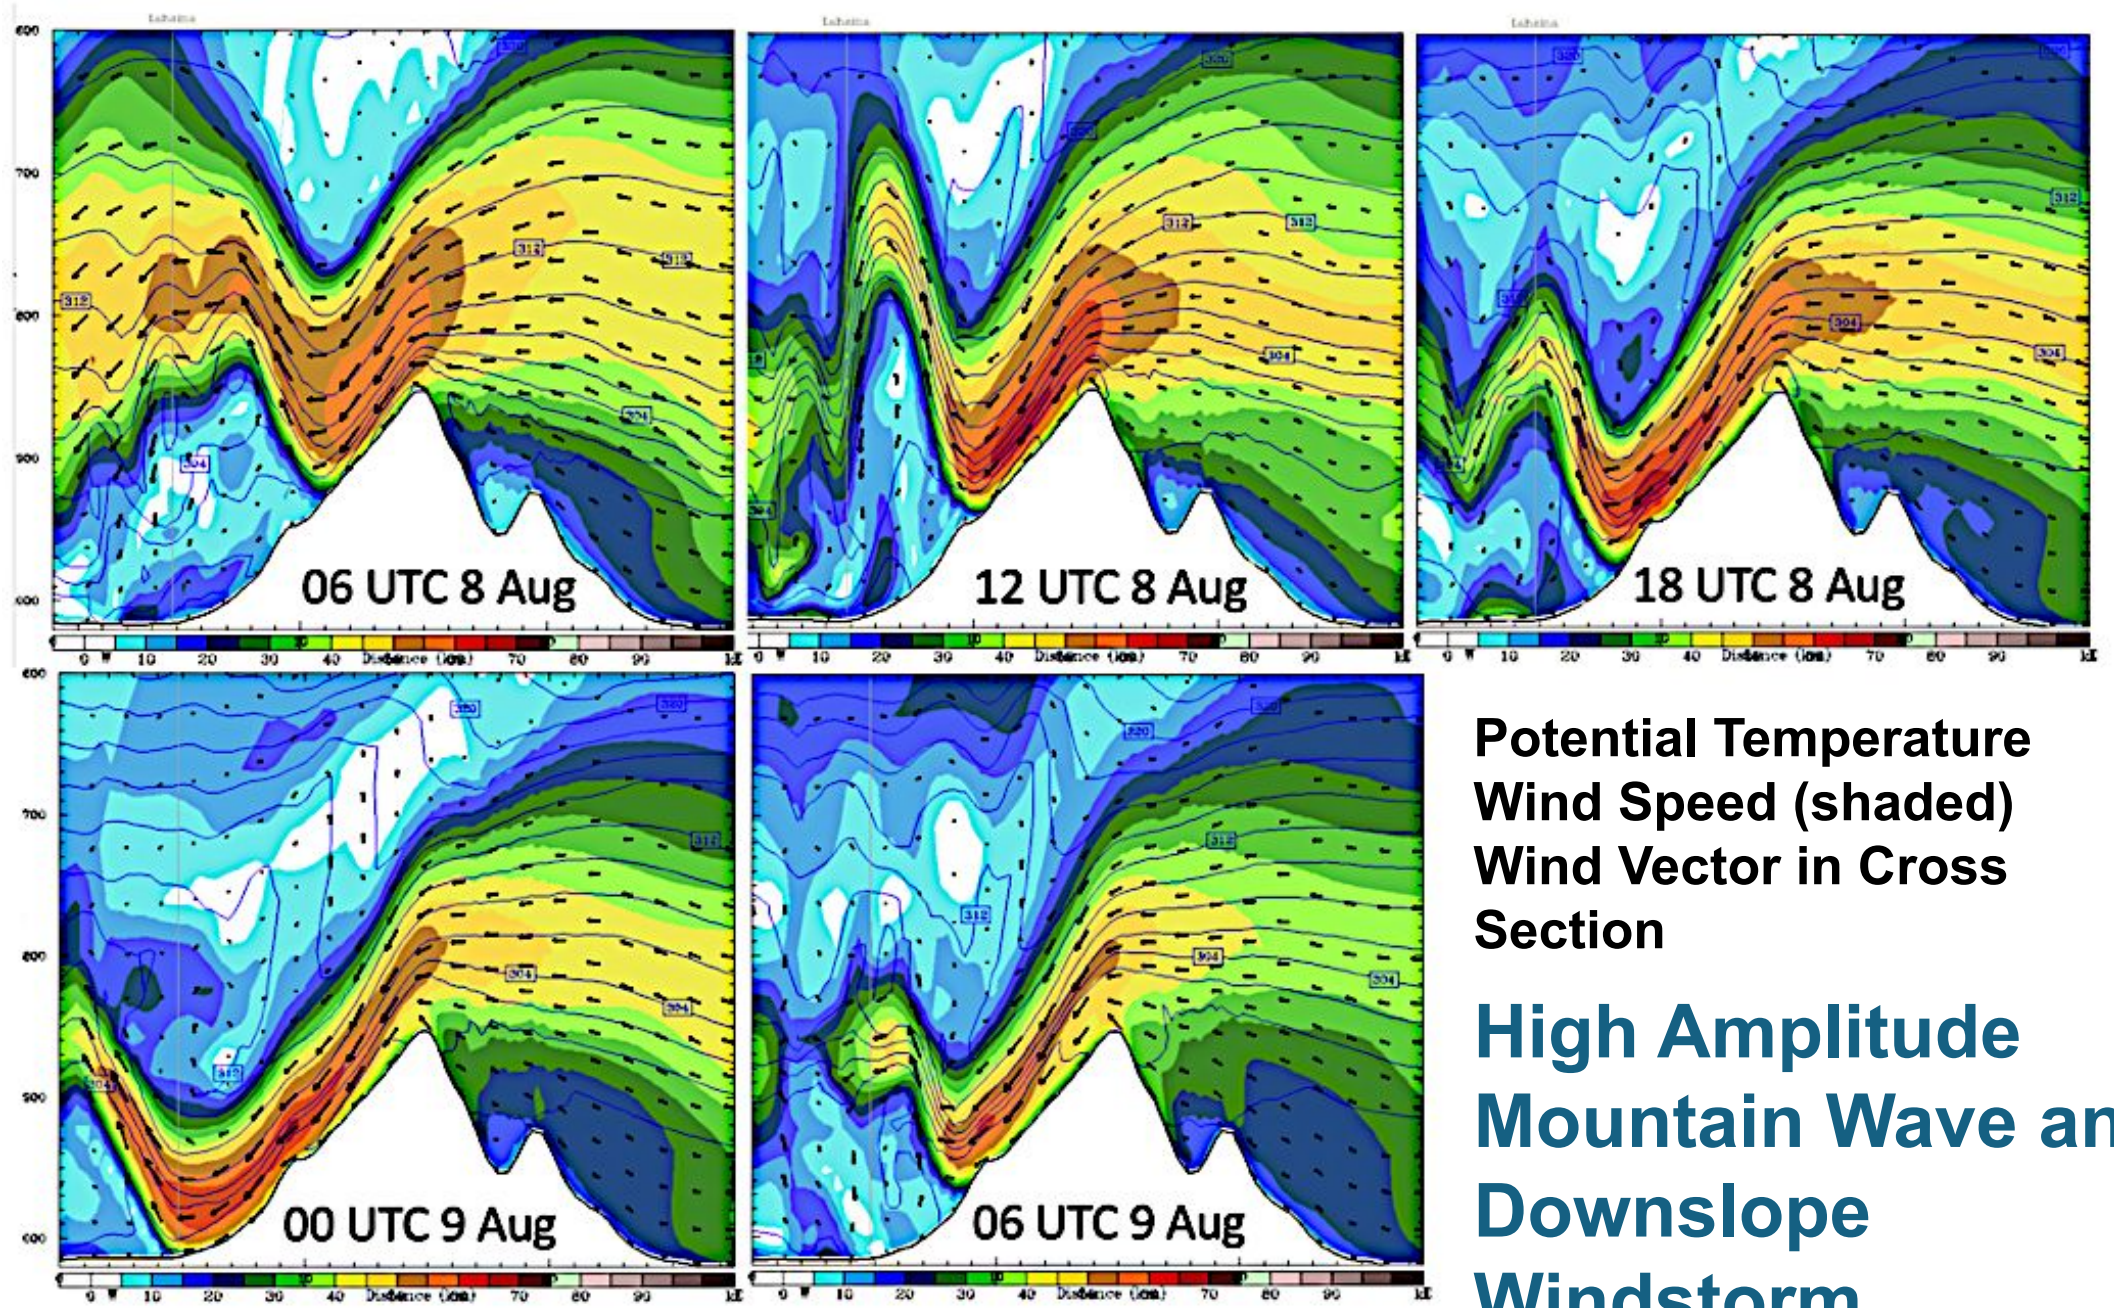

24-h forecast was excellent

Near Perfect Forecasts of the Event

Looking into the Future

The NWP modeling community has **not** caught up with the improved global analyses and data assimilation made possible by the RO community and others.

Why are modelers behind you?

One Reason: Most global models parameterize convection

- Convective parameterizations are **all** problematic and inadequate
- There is **extensive evidence** that convective-allowing resolution in global models, with convection simulated explicitly, is MUCH more skillful.

Convection Permitting Global Prediction: Evaluation for Operational Application

Major Increases in Week 3-4 Forecast Skill With Explicit Conversion

**Only a matter of time before
all global NWP models are
run at convection-allowing
resolution with explicitly
modeled convection**

**Forecast skill will increase,
with better use of the
potential of satellite-based
data**

But there is something else.....

More proof that current models are not taking advantage of all the potential skill in current analyses/initializations

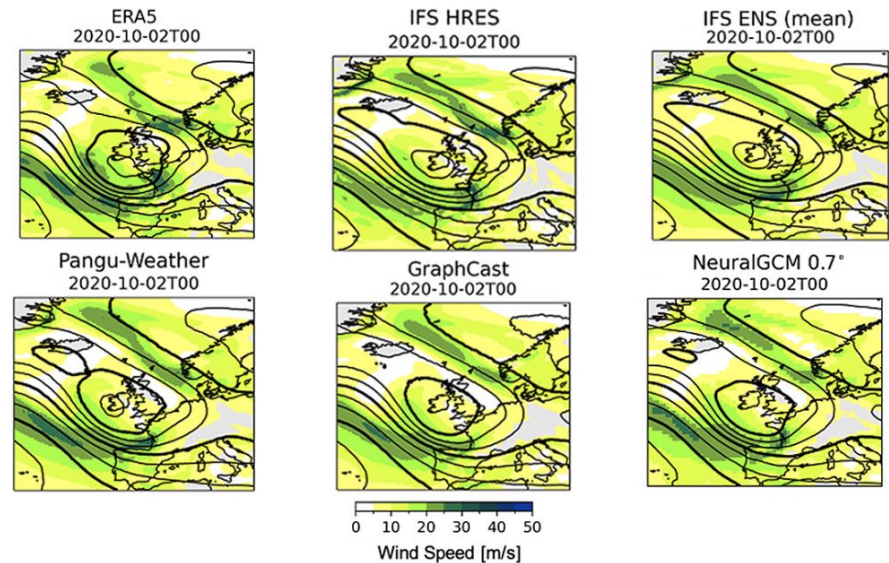

The Implications of Machine Learning NWP

Machine Learning Masters Weather Prediction

Community datasets and evaluation standards are needed to further advance machine learning for weather prediction.

By Hannah Christensen

10 July 2024

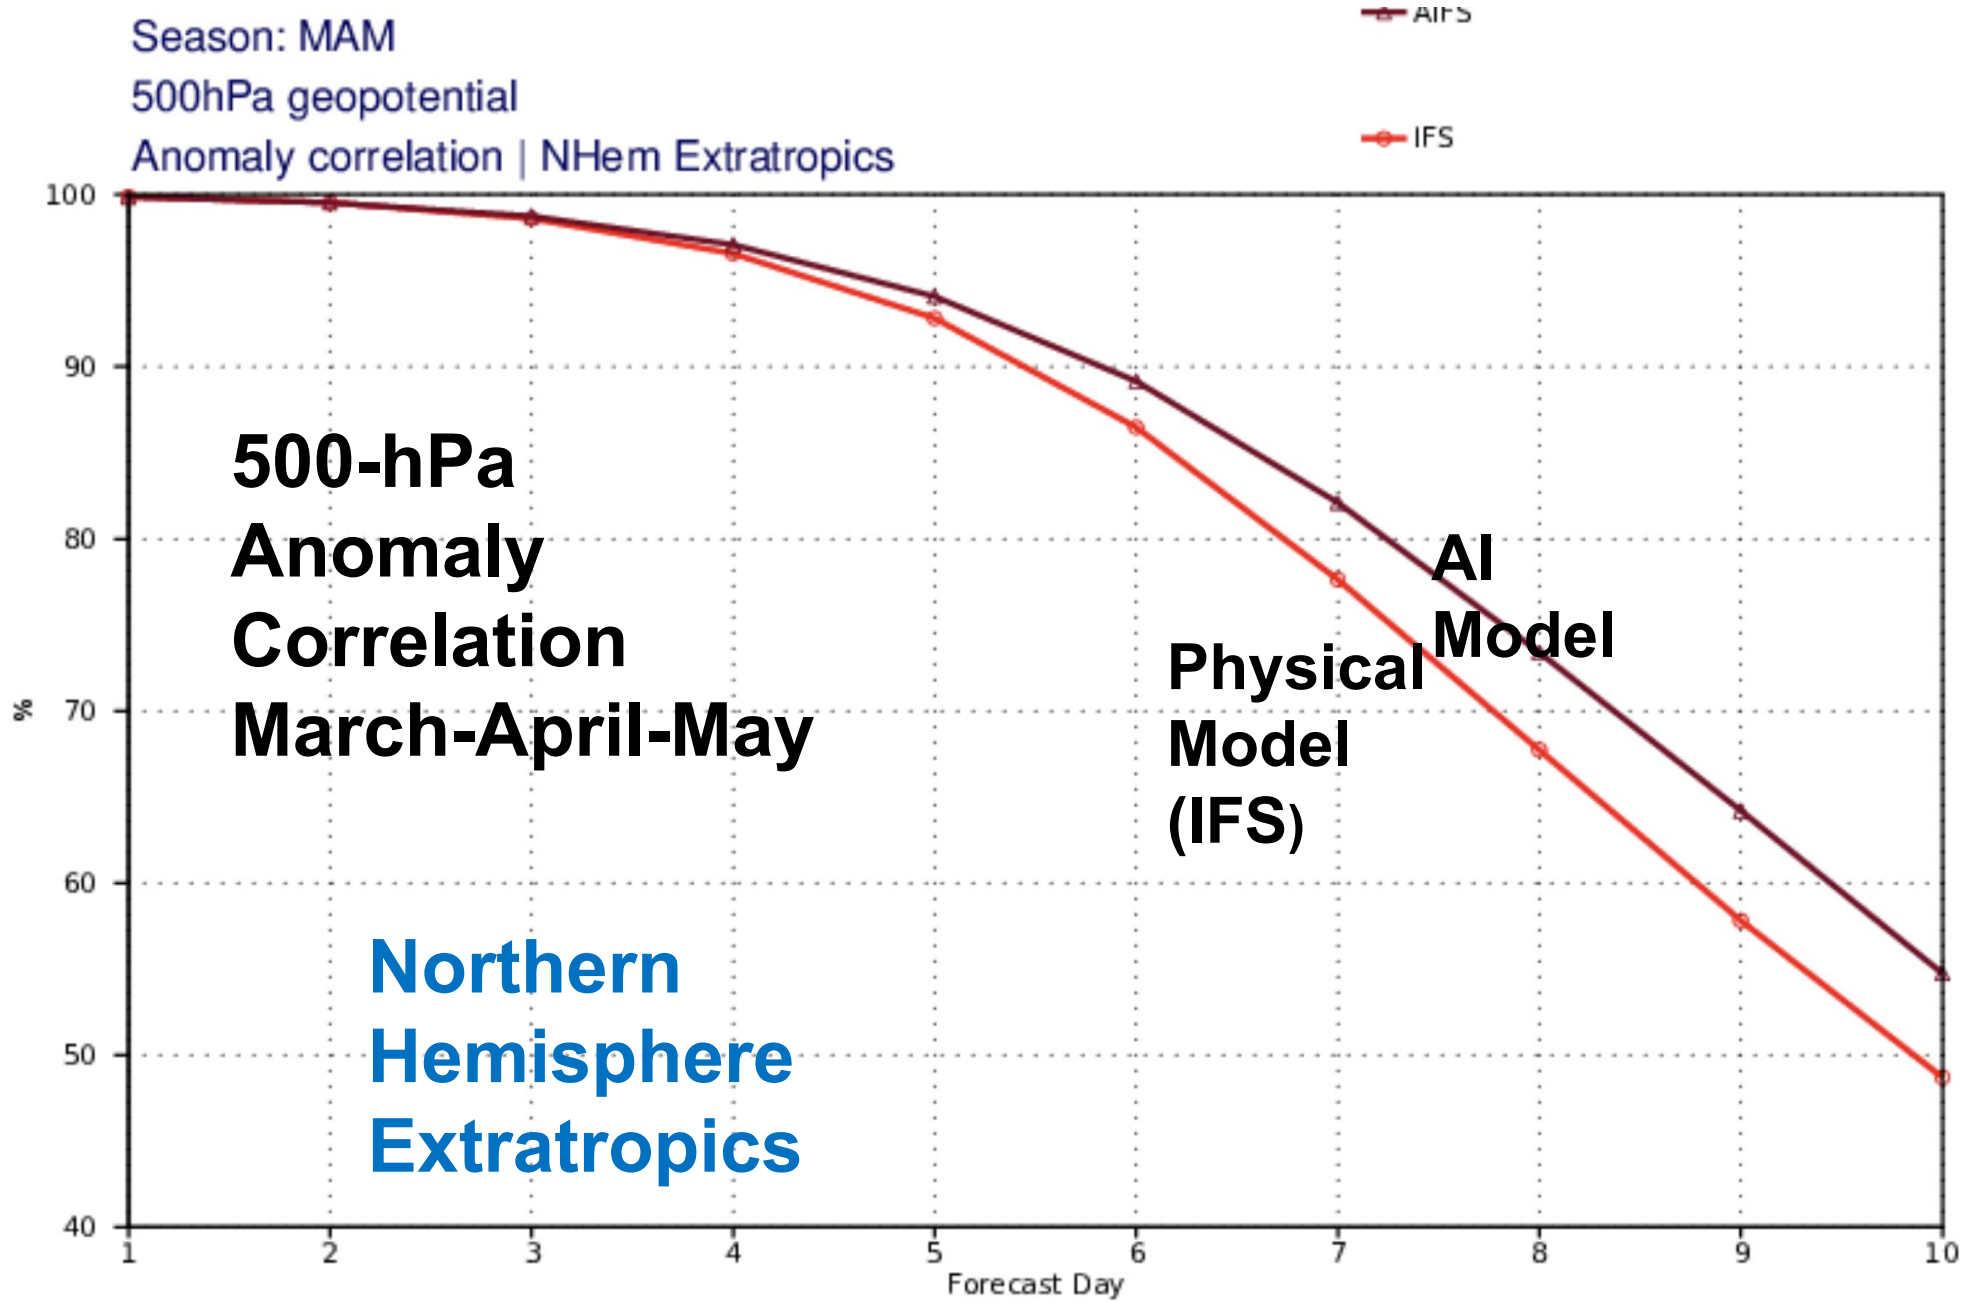

Machine Learning Appears to be More Skillful than Traditional Global NWP Models

Implications:

- There is a a lot more skill that be squeezed out of our current initial conditions!
- Today's physical global models have deficiencies that have prevented them from deriving maximum skill from improved descriptions of the initial state

EC

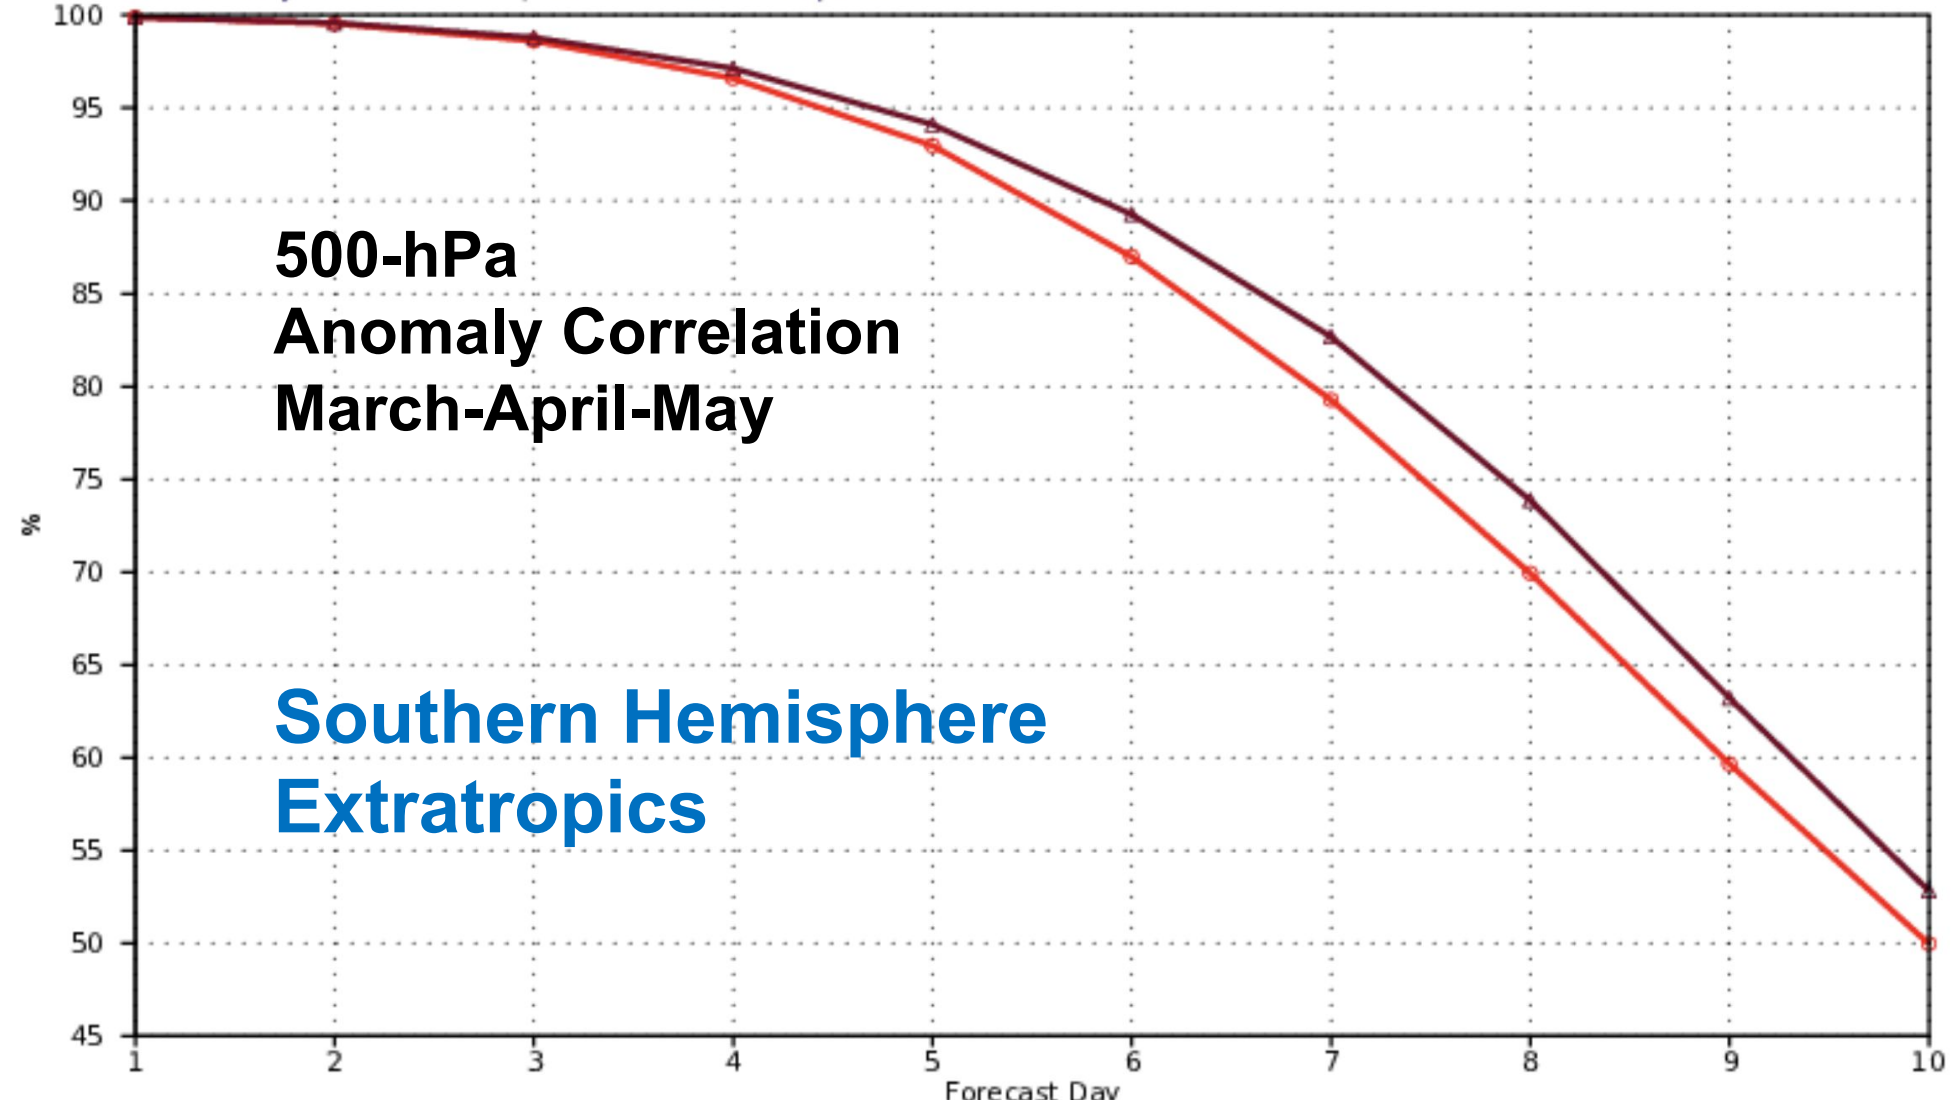

Season: MAM

IFS

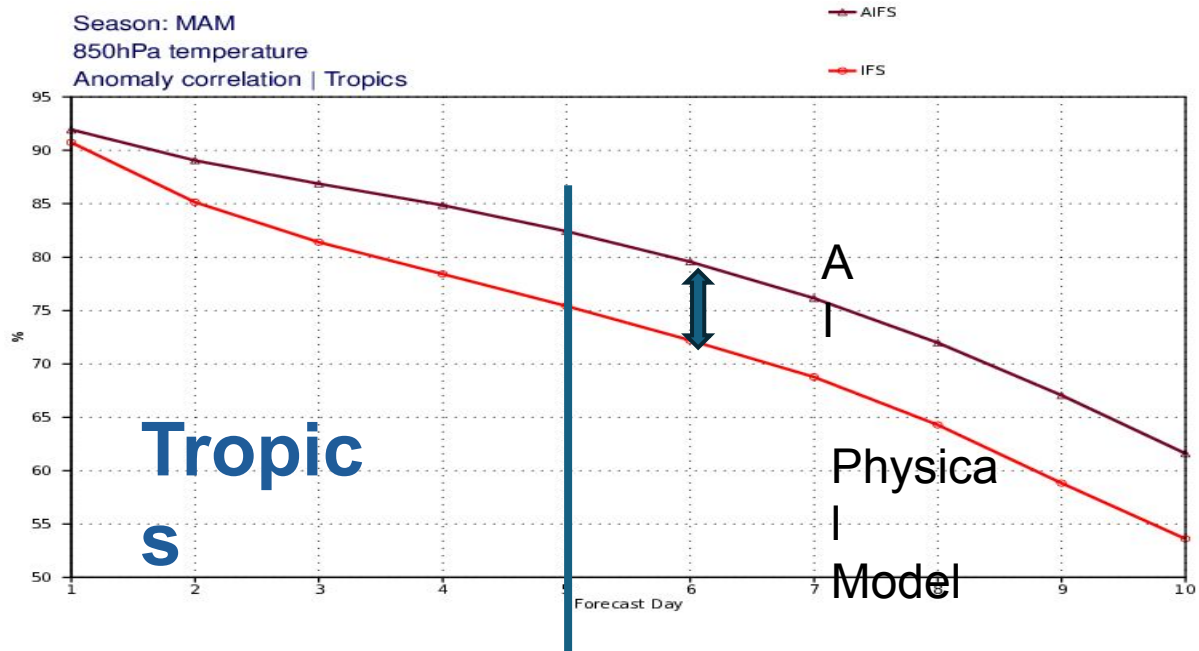

IFS

**500-hPa
Anomaly Correlation
March-April-May**

**Southern Hemisphere
Extratropics**

The Tropics Versus Northern Hemisphere: 850 hPa temperature

AI NWP is relatively far more skillful in tropics compared to traditional models.

Could this be true because convection is far more important in the tropics?

Possible implication: AI is doing better with the aggregate effects of convection

Tropics

Important Point

Either convection-allowing global physical models or AI models will allow global NWP to make better use of the improved initial state that the RO and satellite community are providing

There is substantial room for improvement

Eventually, the modeling community will catch up to you....so the RO and DA communities need to keep ahead

One final note

- Current AI NWP is trained on analyses, such as ERA-5
- If observations are dense enough from RO and other satellite sensors, could AI-NWP be trained directly on observations or gridded versions of observations?

Summary

- **Increased satellite assets, such as RO, have led to a rapid increase in large-scale forecast skill in NWP during approximately 1995-2008, followed by a subsequent leveling off**
- **Mesoscale forecasting skill continued to increase rapidly due to increasing resolution and improved physics.**
- **Operational NWP has not not caught up to the potential of current global analyses.**
- **Convection-allowing global modeling and AI NWP are two approaches to “catch up” and greatly improve forecast skill.**

“NOW THIS IS NOT THE
END. IT IS NOT EVEN
THE BEGINNING OF
THE END. BUT IT IS,
PERHAPS, THE END OF
THE BEGINNING.”

Winston Churchill
