## GNSS-RO Related work at GMAO

- Operational NWP
  - Assimilation of RO in real-time into Goddard Earth Observing System (GEOS) model
  - Using available suite of operationally available RO including commercial
  
- Reanalysis
  - Development of the new MERRA-21C product
    - Bridge between current MERRA-2 and upcoming MERRA-3
    - Covers the “satellite era” i.e. the 21<sup>st</sup> Century
    - Assimilating high-volume Commercial RO from CSDA archive
    - Globally 5-20 thousand profiles/day from Spire alone

## Outline of Presentation

1. Evaluation of GNSS-RO Observation Uncertainty (Error) Model & QC Methods in GEOS
2. Progress & initial results from GMAO’s contribution to Radio Occultation Modeling Experiment (ROMEX)

# Evaluation of GNSS-RO Observation Uncertainty Model & Quality Check Method in GEOS

In data assimilation (DA) the following cost function is minimized:

$$J(x) = \frac{1}{2} [(x_b - x)^T \mathbf{B}^{-1} (x_b - x) + (y - \mathcal{H}(x))^T \mathbf{R}^{-1} (y - \mathcal{H}(x))]$$

Obs error (uncertainties) are contained in the **R** matrix

where:

$x$  = analysis to be found

$x_b$  = model 1<sup>st</sup> guess

$y$  = observation

$\mathcal{H}(x)$  = forward model

**B** = background error covariance

**R** = observation error covariance

The larger the uncertainty assigned to a given observation, the less closely the model analysis produced by DA draws to the given observation.

An *observation uncertainty model* is the method of estimating the uncertainty used in the above cost function for a given observation.

The *quality control (QC) method* applied to the observations is also an important factor in how observations are actually used by the NWP system.

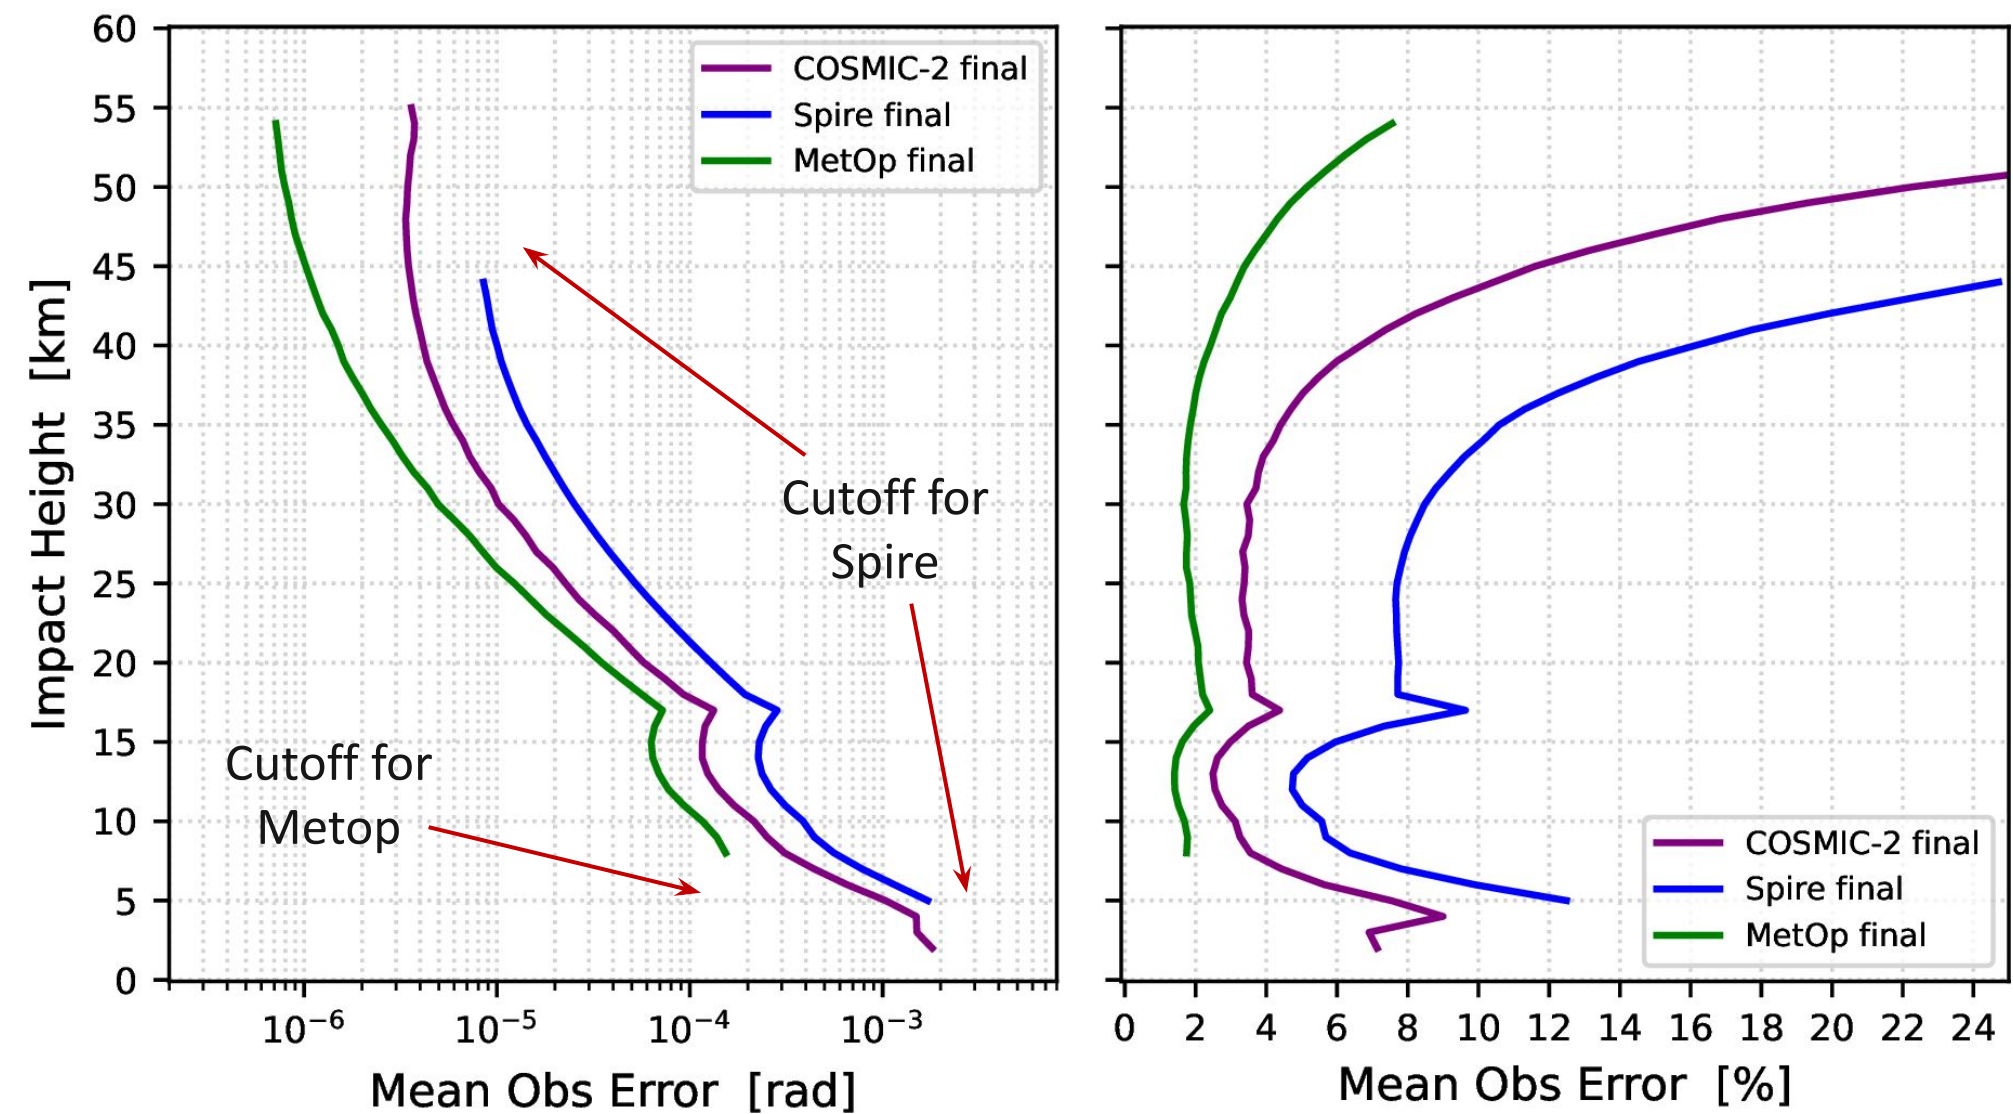

## The Current obs uncertainty model in GEOS

- Based on fit to estimated error using Desroziers method
- Varies by impact height, latitude, & processing center
- Inflated obs errors (factor of 2) for commercial constellations
- “superobbing” inflated by  $N^{1/2}$  where N is the number of RO obs in a single layer

## The Current Quality Control method in GEOS includes:

- Gross error check
  - innovations/E > 10
- Statistical check:
  - OMB/O > X  $\sigma$  ( $\sigma$  varies with 3 regions, transition zones +/- 1 km between regions.  $\sigma$  specified via statistical fit to observed  $\sigma$  based on two months of data)
- Mission specific height cutoffs
  - No MetOp below 8 km
  - No commercial below 5 km & above 45 km

All Occultations over 40°N to -40°N  
at 0000 UTC 2021-12-12

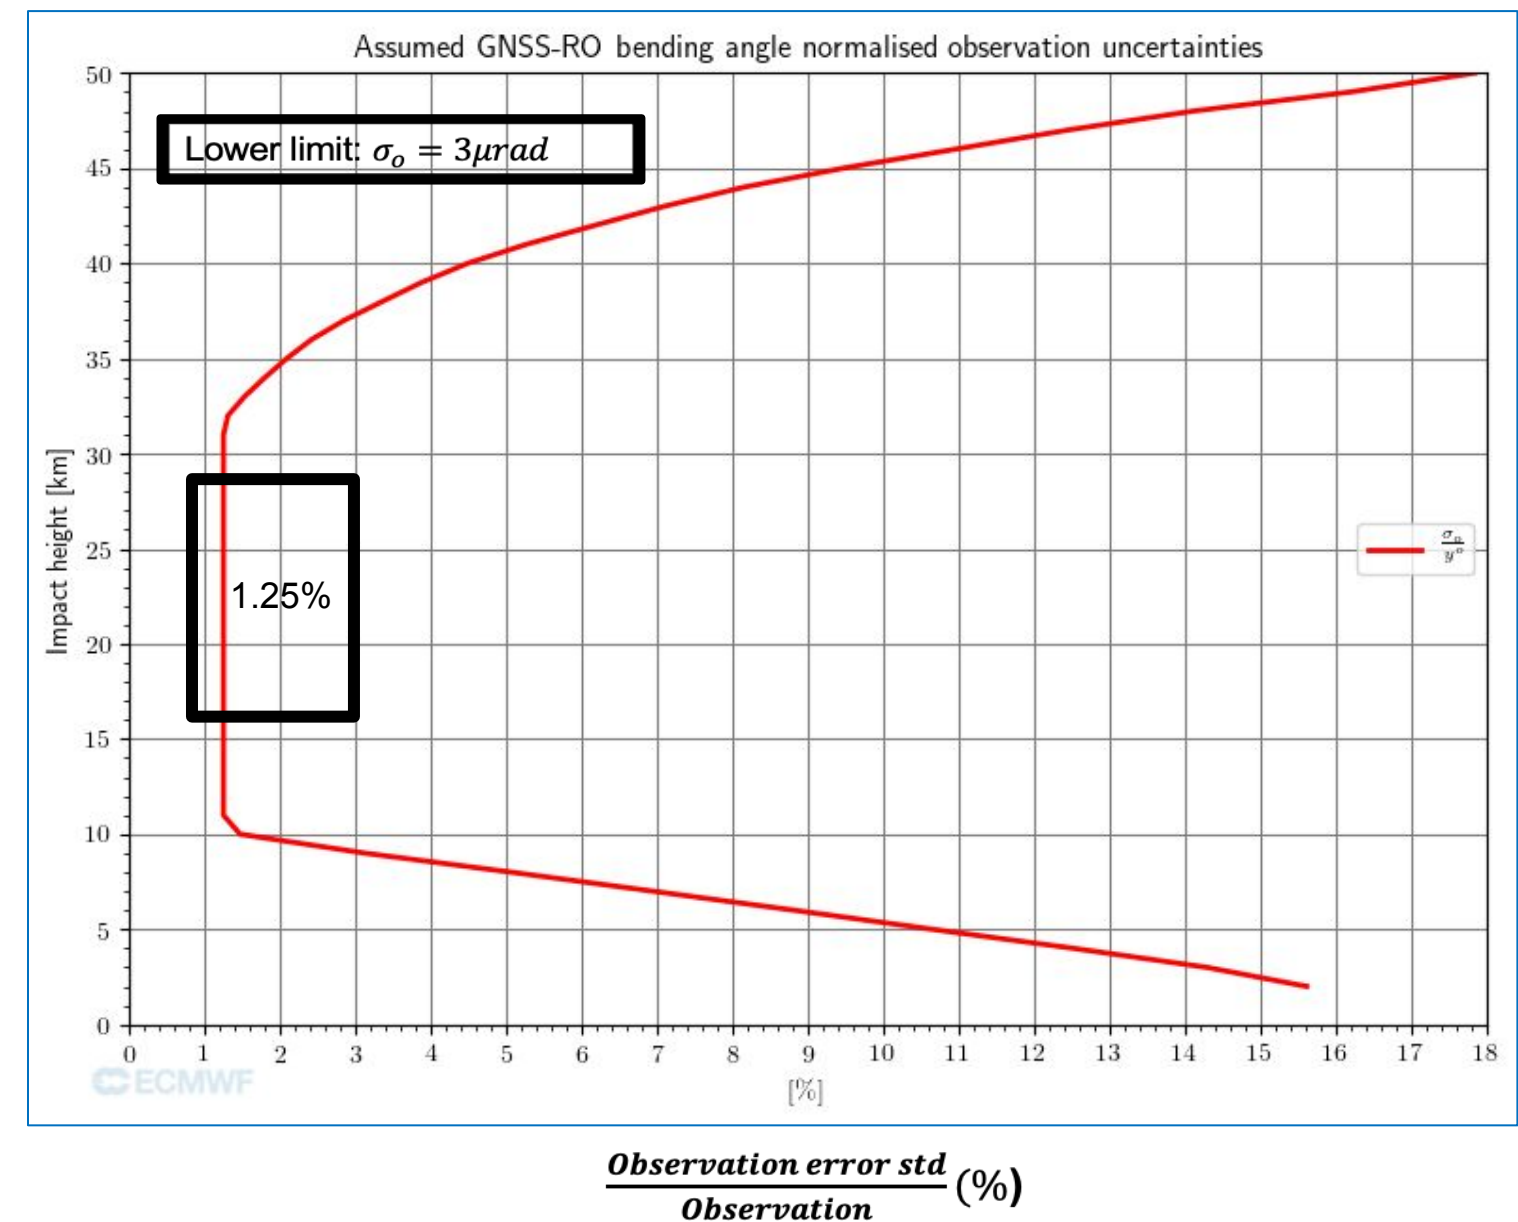

## The ECMWF RO observation uncertainty model

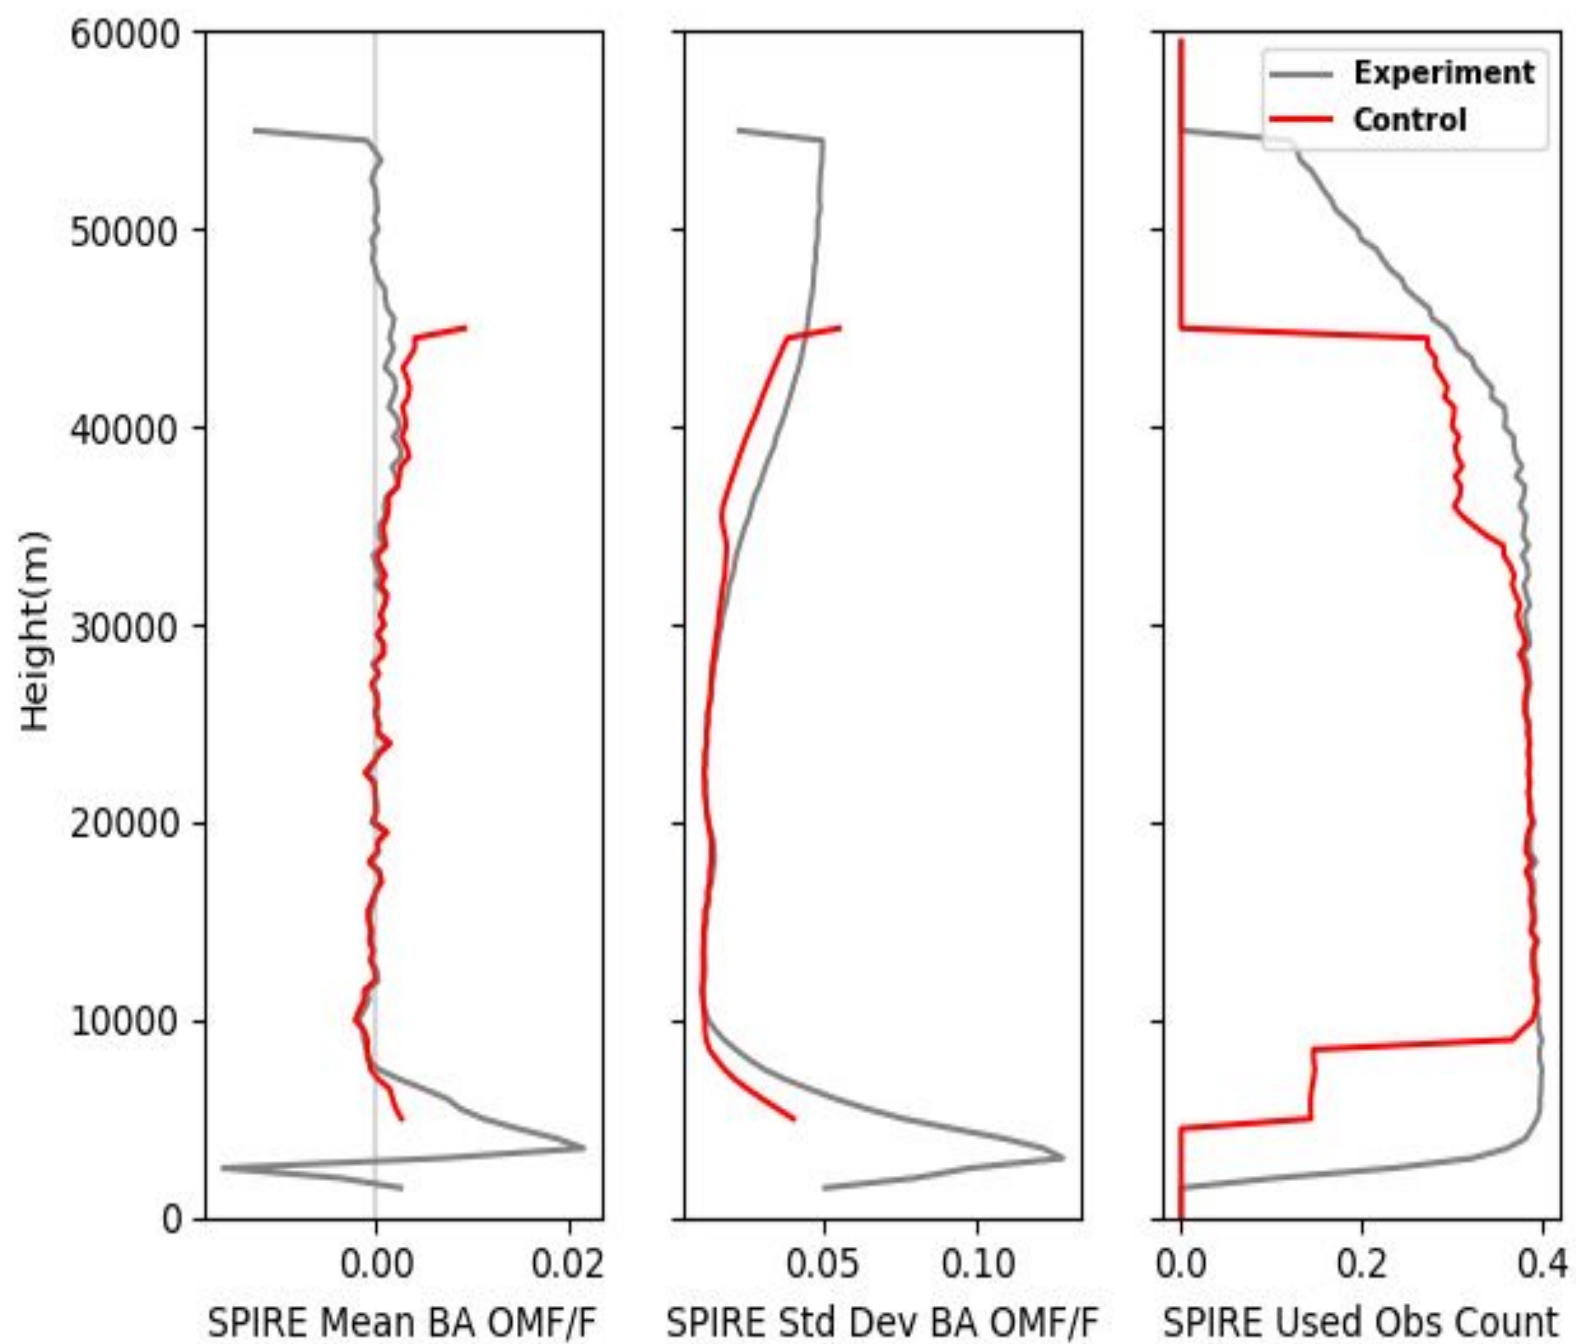

- Dependent only on impact height
- Independent of mission/latitude etc
- Error correlations in vertical are ignored

## The ECMWF RO Quality Control method includes:

- Reject if the innovation is larger than 7 times standard dev of the obs ( $\sigma_o$ )
  - $\text{abs}(o-b) > 5 \sqrt{(\sigma_o^2 + \sigma_b^2)} = 5\sqrt{2}\sigma_o^2 \approx 7 \sigma_o$ .
- No upper/lower boundary cutoffs.

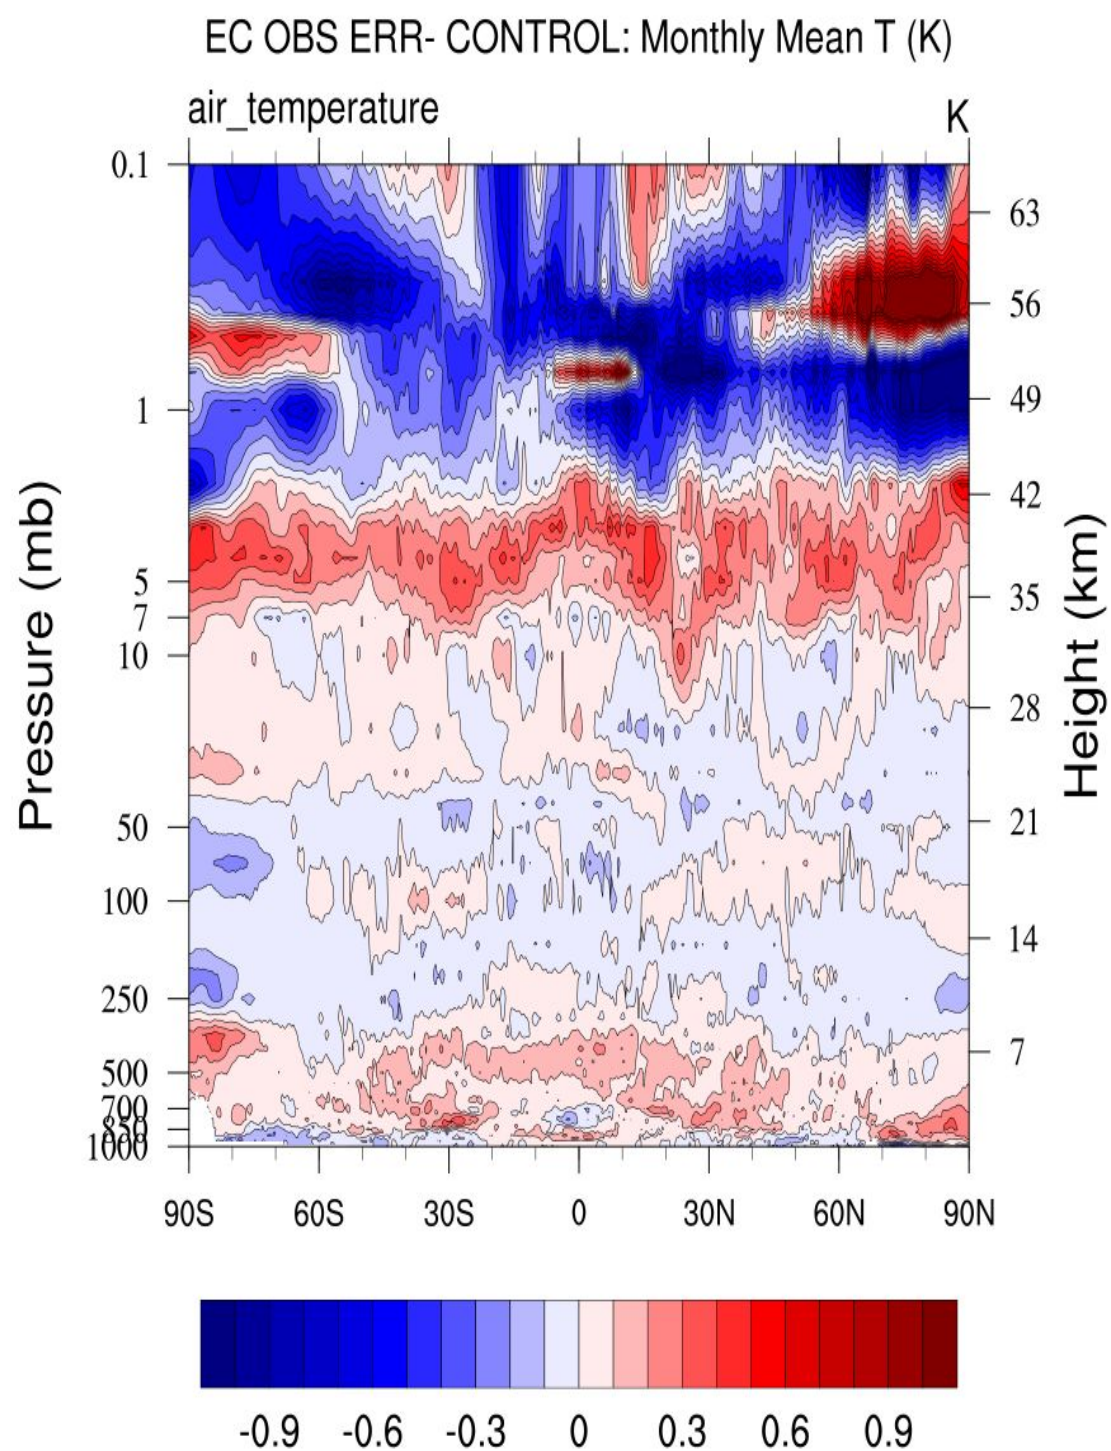

## SPIRE

## COSMIC2

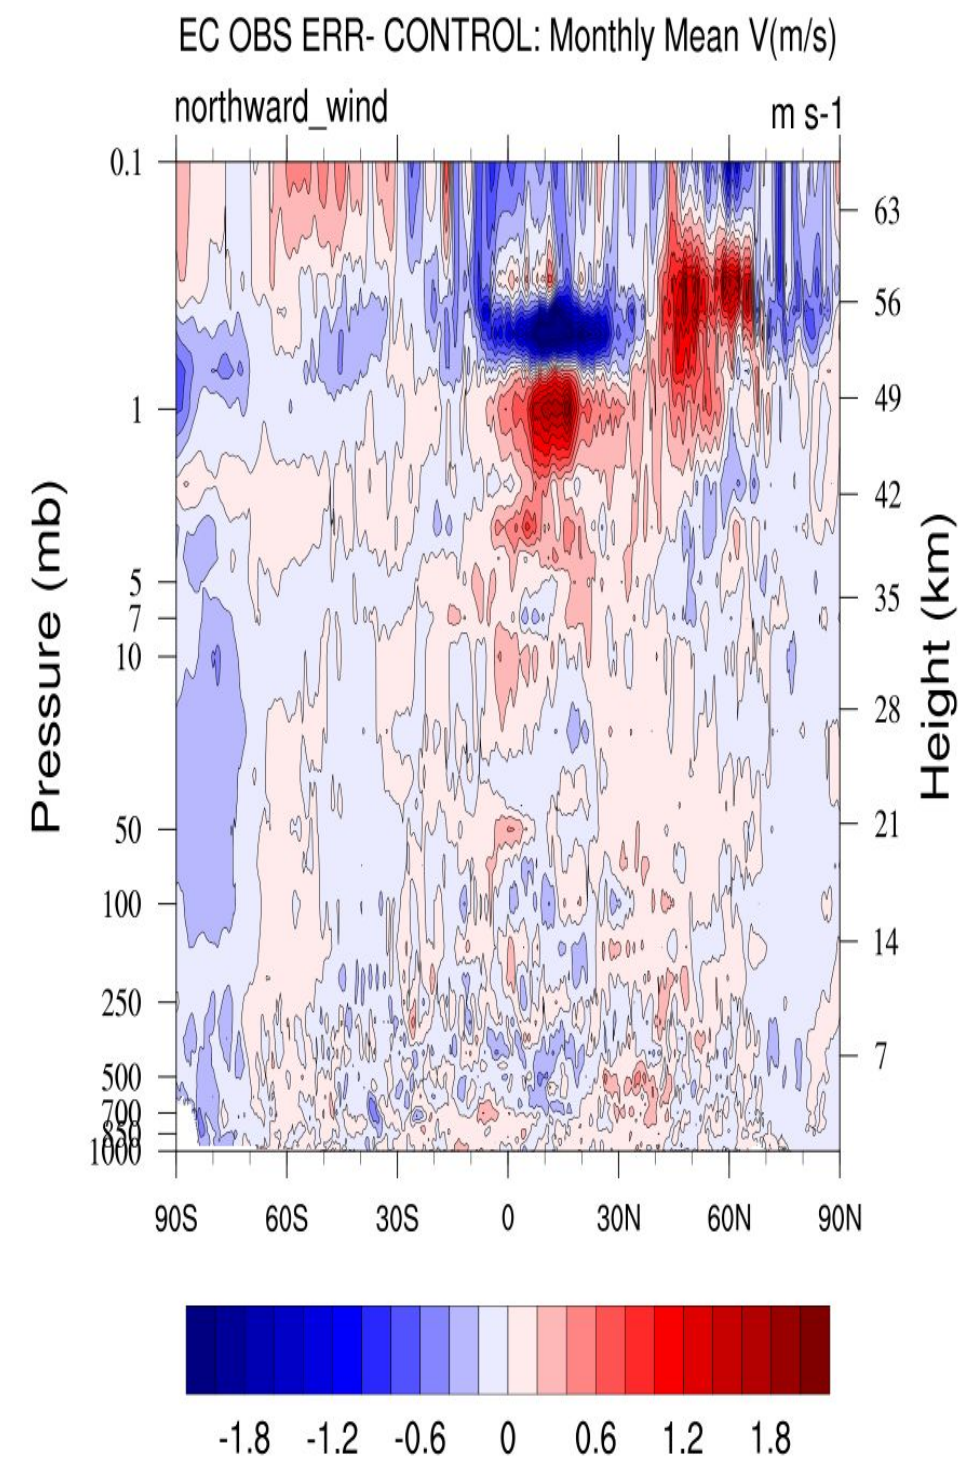

## Temperature

## U Wind Comp

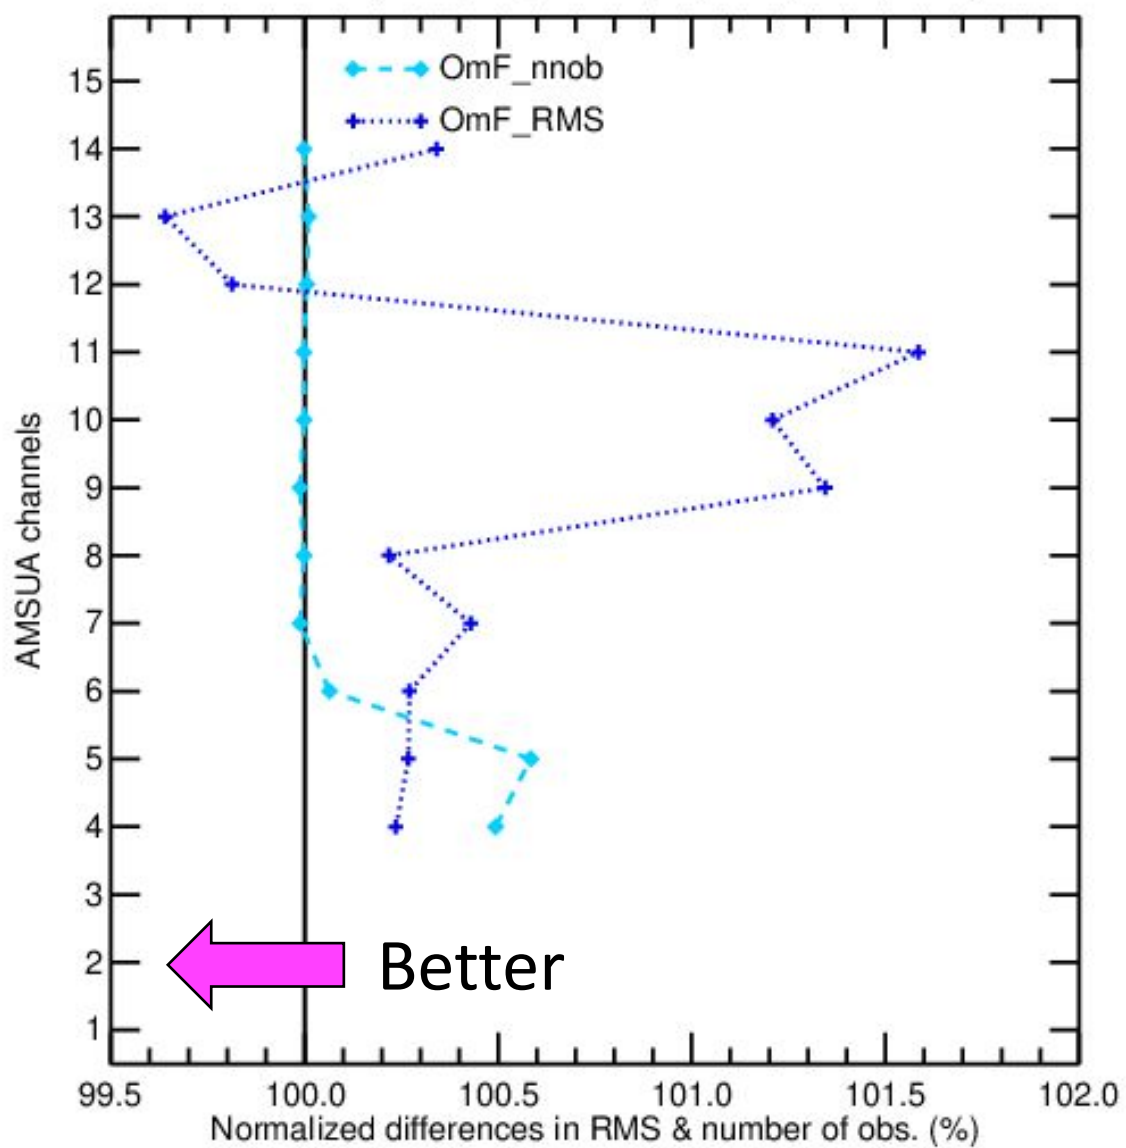

## V Wind Comp

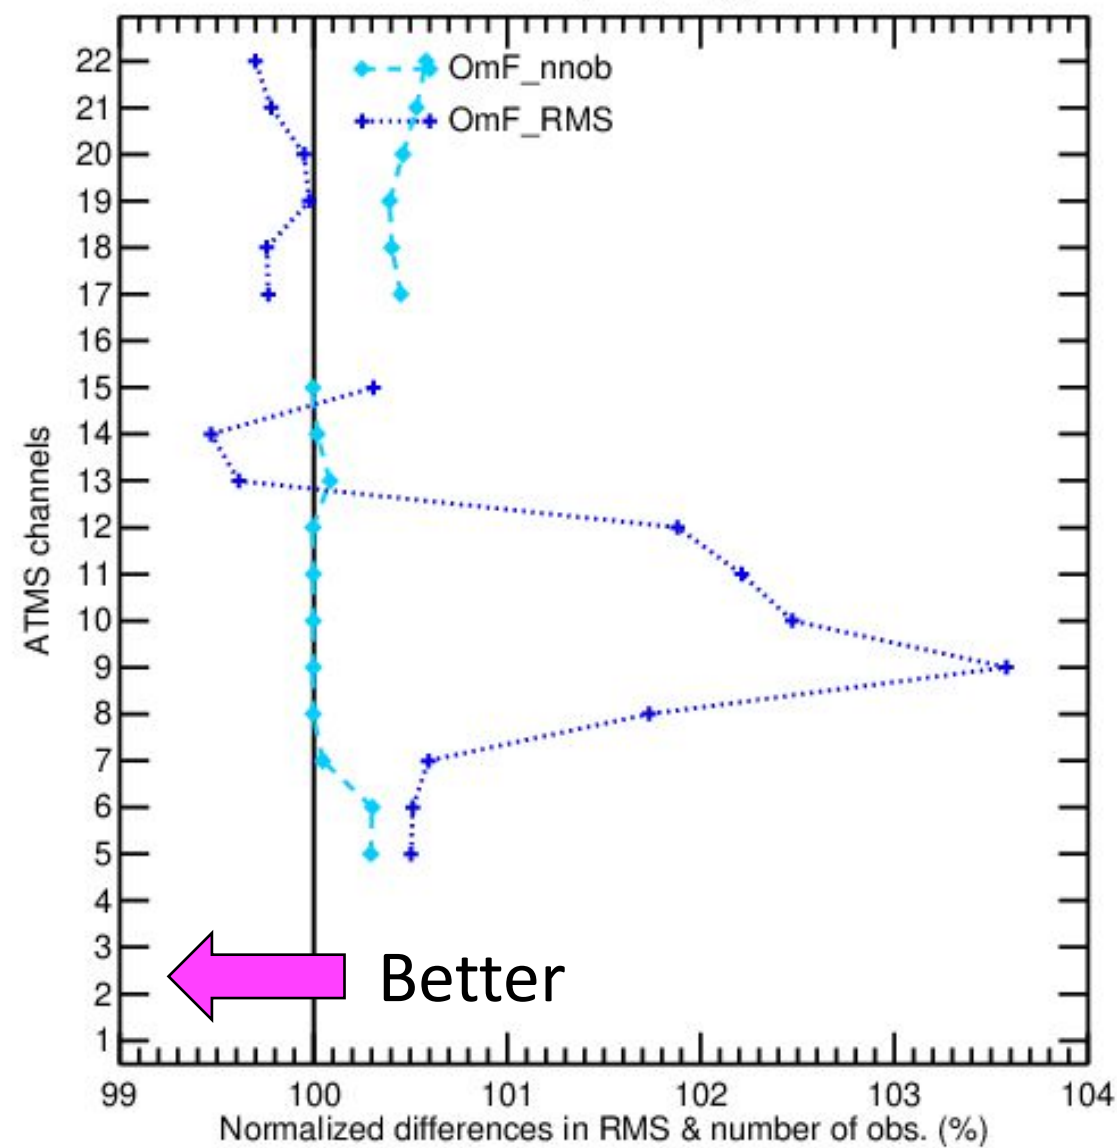

Large differences in the analyses between the experiment (using the ECMWF method) and the Control. Especially above ~35 km

## AMSU-A

## ATMS

Degraded performance with experiment using EC Obs  
Uncertainty & QC Model with both instruments

# Progress & initial results from GMAO's contribution to ROMEX

## ROMEX seeks to answer

- What is the impact of greatly increased volume of RO observations on NWP forecasts?

## GMAO's Model Configuration

- NASA's GEOS Atmospheric Data Assimilation System (ADAS) version 5.30.3 (X0048)
- Resolution of 25 km in horizontal & 72 layers in vertical
- Primary model initialization at 00 & 12 UTC (longer forecasts)
- Additional model initialization at 06 & 18 UTC (shorter forecasts)

## GMAO's RO Specific Configuration

- NBAM Observation operator
- Standard GEOS Observation Error Model & QC

## Current status of NWP runs

- Completed the first month (September 2022) of the 3 month ROMEX period

ROMEX Data Volume (estimated)			For 20220906	
Mission	RO/day	Control	Control	Experiment
GRAS	1,200	y	1194	1194
COSMIC-2	6,000	y	5220	5220
Spire	17,000	n		17337
GNOS	2,100	n		2080
PlanetiQ	3,200	n		2900

Sum ROMEX	37300	n		34553

## Extra tropics (Southern)

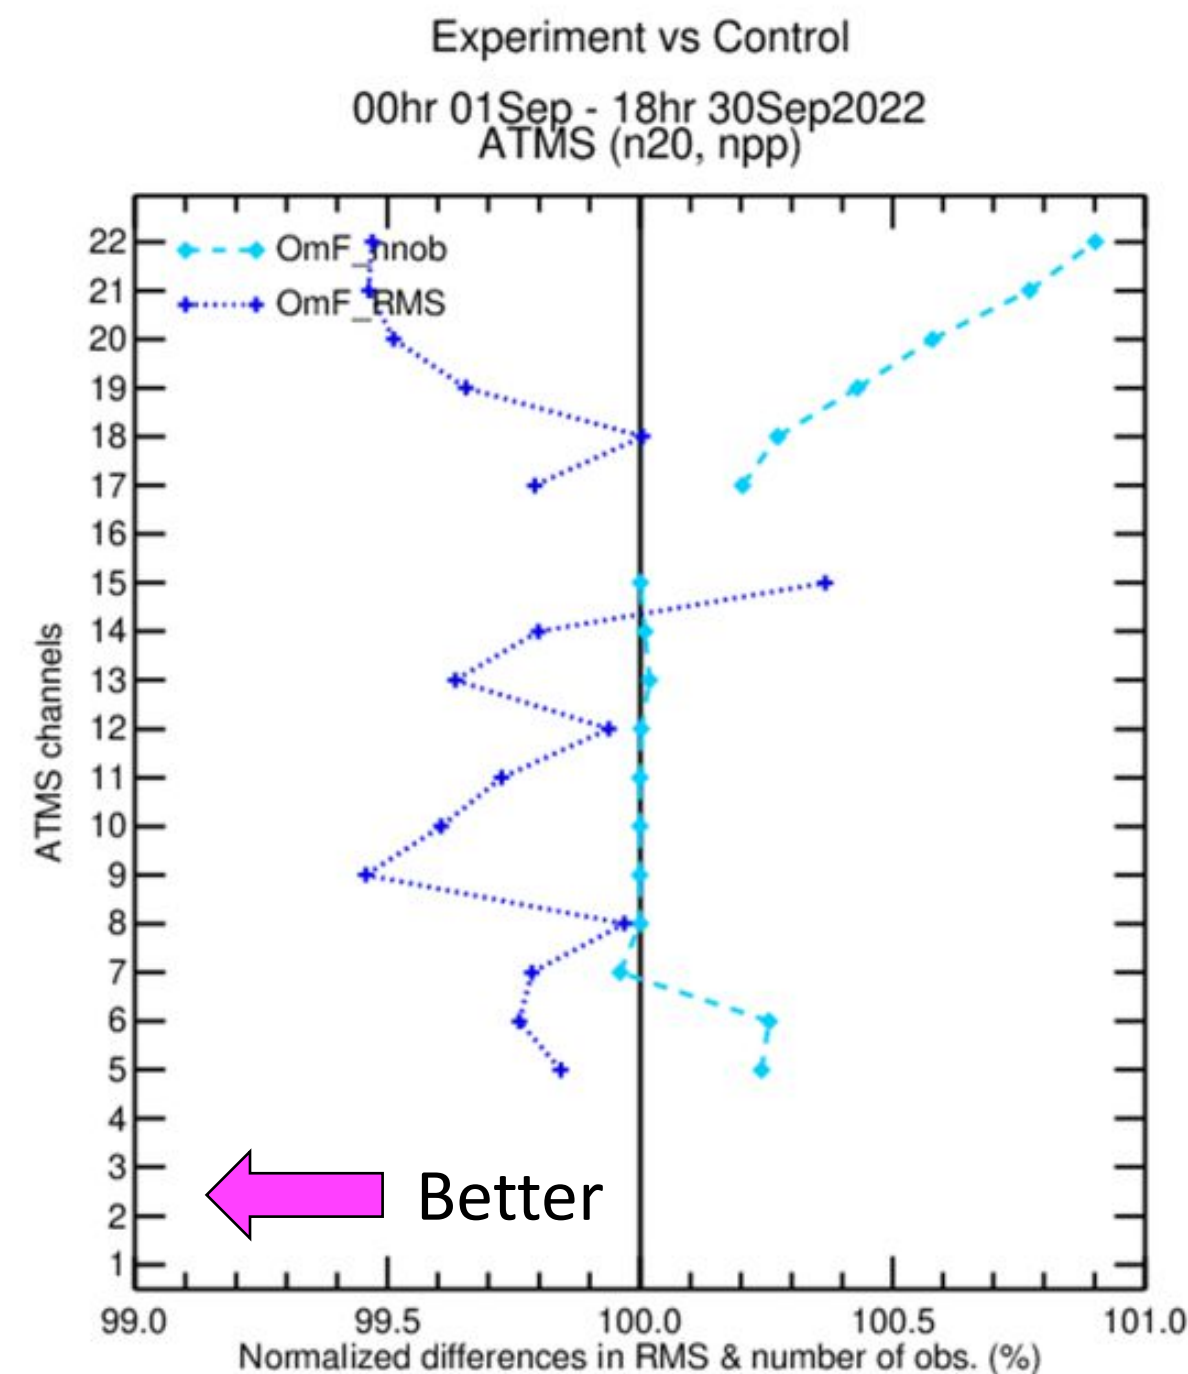

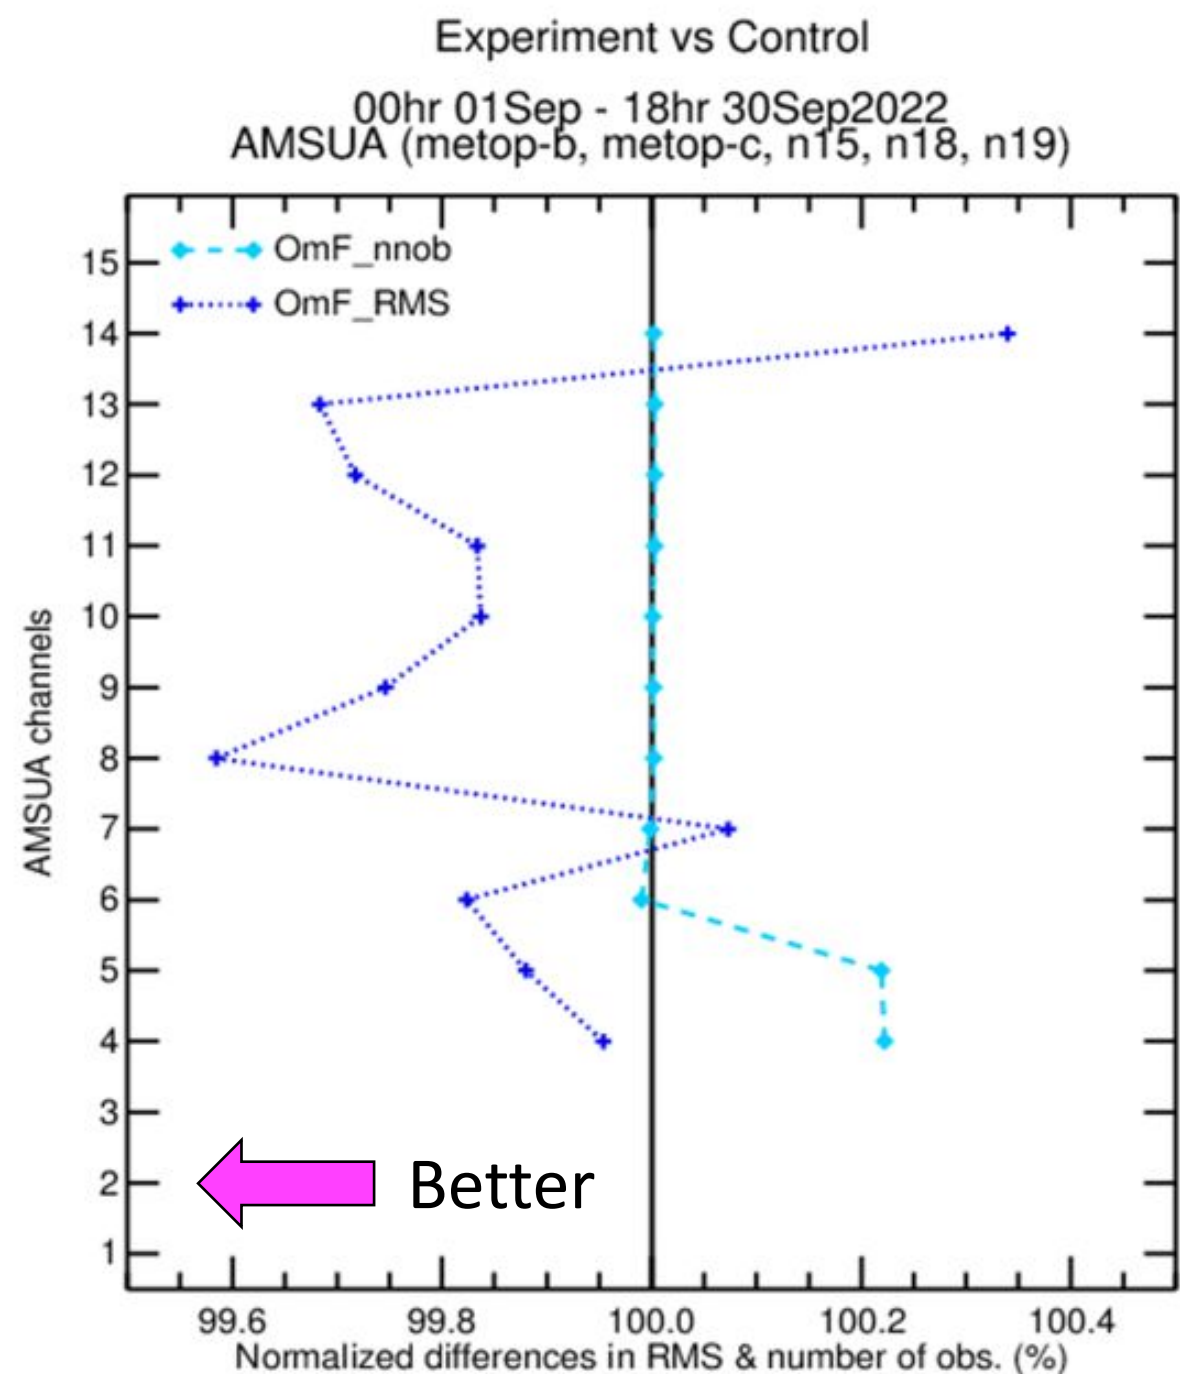

## Tropics (40N to 40S)

Example from a single day (06 September 2024)

# Comparison Between ROMEX Control and Experiment: Microwave Instruments

There is an improvement in the performance of the MW instruments with the assimilation of commercial GNSS-RO data where the RMSE is reduced for mostly all channels, except Channel 14. Channel 14 is not bias corrected in the GMAO systems.

- Forecast Sensitivity-based Observation Impacts (FSOI)

- Utilizes the components of a variational DA system
- Provides impact of any observation or group of obs
- Impact is on accuracy of short-term (usually 24 hour forecast)
- Computationally inexpensive (relatively)

- Potential applications

- Impact of commercial RO as a whole
- Impact of individual constellations/satellites

- Initial results are promising for ROMEX

- Larger fraction impact for Experiment

**Results for Northern Hemisphere 20N to 90N**

- Forecast Sensitivity-based Observation Impacts (FSOI)

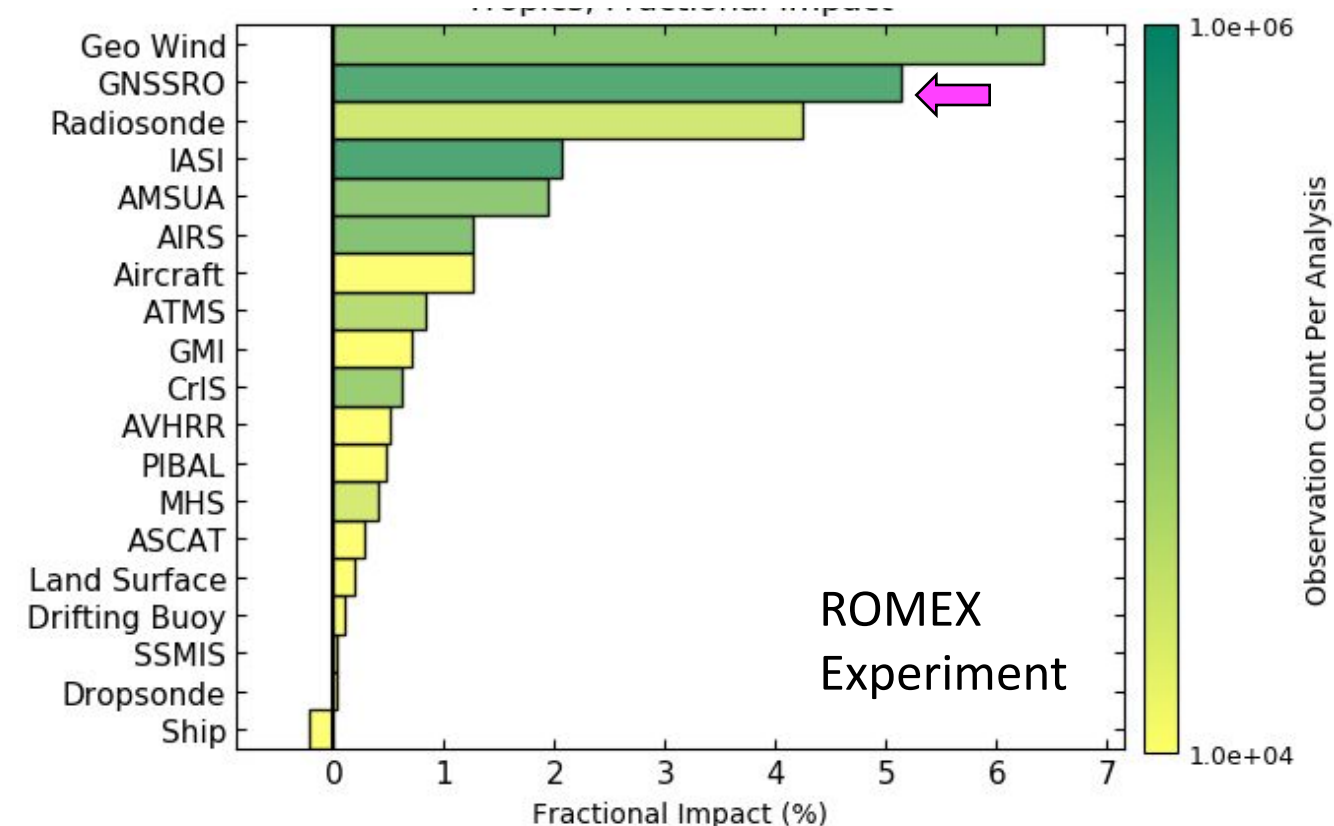

- Utilizes the components of a variational DA system
- Provides impact of any observation or group of obs
- Impact is on accuracy of short-term (usually 24 hour forecast)
- Computationally inexpensive (relatively)

- Potential applications

- Impact of commercial RO as a whole
- Impact of individual constellations/satellites

- Initial results are promising for ROMEX

- Larger fraction impact for Experiment
  - Less in tropics

**Results for  
Tropics  
20N to 20S**

## Example of type of forecast evaluation

- Forecast skill card
  - Southern Hemisphere only
  - Forecasts out to 5 day
  - Main pressure levels

### Legend

- ▲ far better, significant (99.99% confidence)
- △ better, significant (99% confidence)
- ▤ slightly better, significant (95% confidence)
- no significant difference
- ▥ slightly worse, significant (95% confidence)
- ▽ worse, significant (99% confidence)
- ▼ far worse, significant (99.99% confidence)

Example of Forecast Skill Card

## Observation uncertainties & QC method for RO

- GMAO is experimenting with different methods
  - One goal is to use more of the available RO observations in the DA system
- Initial results suggest the method used by the ECMWF is not improving over the method currently used in GEOS
  - Further investigation is currently being carried out
  - Potentially related to QC criteria

## The Radio Occultation Modeling Experiment (ROMEX)

- GMAO is participating in ROMEX along with multiple operational NWP centers
- Initial results are encouraging
  - Commercial RO obs are of good quality
  - Increased volume of RO obs appears to be improving the analyses and short term forecast
- Further work investigating the impact of the forecast will be carried out
  - Results will be compared with other operational NWP centers
